Selection Model

Jason Qiang Guo, New York

Tobit Model: MLE

- Basic setup:

$$\underbrace{y_i^*}_{1\times 1} = \underbrace{x_i'}_{1\times K}\underbrace{\beta}_{K\times 1} + \underbrace{\varepsilon_i}_{1\times 1}$$

where

$$\varepsilon_i | x_i \sim N\left(0, \sigma^2\right).$$

The dependent variable y_i^* is determined by

$$y_i = \begin{cases} y_i^* & : \text{ if } y_i^* > 0 \\ 0 & : \text{ if } y_i^* \leq 0 \end{cases}.$$

Tobit Model: MLE

- Basic setup:

$$\underbrace{y_i^*}_{1\times 1} = \underbrace{x_i'}_{1\times K}\underbrace{\beta}_{K\times 1} + \underbrace{\varepsilon_i}_{1\times 1}$$

where

$$\varepsilon_i | x_i \sim N\left(0, \sigma^2\right).$$

The dependent variable y_i^* is determined by

$$y_i = \begin{cases} y_i^* & : \text{ if } y_i^* > 0 \\ 0 & : \text{ if } y_i^* \leq 0 \end{cases}.$$

- In order to estimate this model, we need to derive the conditional distribution density function of y_i, i.e. $f(y_i|x_i)$. And we have to consider two cases for this model: (i) $y > 0$ and (ii) $y = 0$.

Tobit Model: MLE

(i) Case of $y_i > 0$

The above definition of y_i indicates that if $y_i > 0$ the conditional distribution of y_i is the same as that of y_i^*. Therefore, if $y > 0$, we have

$$
\begin{aligned}
f(y_i|x_i) &= f^*(y_i|x_i) \\
&= f^*(y_i^*|x_i) \qquad (\text{since } y_i = y_i^* \text{ if } y_i > 0) \\
&= \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{1}{2}\frac{(y_i - x_i'\beta)^2}{\sigma^2}\right) \qquad (\text{since } y_i^* \text{ is distributed normally } y_i^* \sim N(x_i'\beta, \sigma^2)) \\
&= \frac{1}{\sigma}\underbrace{\frac{1}{\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{y_i - x_i'\beta}{\sigma}\right)^2\right)}_{=\phi\left(\frac{y_i - x_i'\beta}{\sigma}\right)} \\
&= \frac{1}{\sigma}\phi\left(\frac{y_i - x_i'\beta}{\sigma}\right). \qquad (\text{since pdf of standard normal is } \phi(z) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{1}{2}z^2\right), \text{ now } z = \frac{y_i - x_i'\beta}{\sigma})
\end{aligned}
$$

Tobit Model: MLE

(ii) Case of $y_i = 0$
On the other hand, for $y_i = 0$, we have the mass conditional probability $\Pr(y_i = 0 | x_i)$ which is equal to

$$\begin{aligned}
\Pr(y_i = 0 | x_i) &= \Pr(y_i^* < 0 | x_i) \\
&= \Pr(x_i'\beta + \varepsilon_i \le 0 | x_i) \qquad \text{(by definition of latent variable } y_i^*,\ y_i^* = x_i'\beta + \varepsilon_i) \\
&= \Pr\left(\underbrace{\varepsilon_i}_{\text{distributed as } N(0,\sigma^2)} \le -x_i'\beta \middle| x_i \right) \\
& \quad \Pr\left(\underbrace{\frac{\varepsilon_i}{\sigma}}_{\text{distributed as standard normal}} \le -\frac{x_i'\beta}{\sigma} \middle| x_i \right) \\
&= \Phi\left(-\frac{x_i'\beta}{\sigma}\right) \qquad \text{(where } \Phi \text{ is the c.d.f. of standard normal)} \\
&= 1 - \Phi\left(\frac{x_i'\beta}{\sigma}\right) \qquad \text{(since standard normal distribution is symmetric, } \Phi(-z) = 1 - \Phi(z)\text{).}
\end{aligned}$$

Therefore, according to the result of (i) and (ii), the conditional density function is expressed as

$$f(y_i | x_i) = \begin{cases} \text{continuous part} & f^*(y_i | x_i) = \frac{1}{\sigma}\phi\left(\frac{y_i - x_i'\beta}{\sigma}\right) \quad : \quad \text{if } y_i > 0 \\ \text{mass part} & \Pr(y_i = 0 | x_i) = 1 - \Phi\left(\frac{x_i'\beta}{\sigma}\right) \quad : \quad \text{if } y_i \le 0 \end{cases}$$

Tobit Model: MLE

- It is now clear that we can write down our MLE object

$$L(\beta, \sigma^2) = \prod_{y_i > 0} \frac{1}{\sigma} \phi(\frac{y_i - x_i' \beta}{\sigma}) \prod_{y_i = 0} (1 - \Phi(\frac{x_i' \beta}{\sigma}))$$

and the covariance-variance matrix is given by

$$I^{-1} = -E(\frac{\partial \log L(\beta, \sigma^2)}{\partial \beta' \beta})$$

Tobit Model: MLE

- It is now clear that we can write down our MLE object

$$L(\beta, \sigma^2) = \prod_{y_i > 0} \frac{1}{\sigma} \phi(\frac{y_i - x_i'\beta}{\sigma}) \prod_{y_i = 0} (1 - \Phi(\frac{x_i'\beta}{\sigma}))$$

  and the covariance-variance matrix is given by

$$I^{-1} = -E(\frac{\partial \log L(\beta, \sigma^2)}{\partial \beta' \beta})$$

- What about conditional expectation $E_{y|x}[y|x]$ and $E_{y|x,y>0}[y|x, y > 0]$? We are interested in the marginal effects of x on y.

Tobit Model: Conditional Expectation

- The calculation involves lengthy mathematical calculation, but the basic idea is that

$$E_{y|x}[y|x] = Pr(y^* \leq 0|x_i)E_{y|x,y=0}[y|x, y = 0] + Pr(y^* > 0|x_i)E_{y|x,y>0}[y|x, y > 0]$$

Tobit Model: Conditional Expectation

- The calculation involves lengthy mathematical calculation, but the basic idea is that

$$E_{y|x}[y|x] = Pr(y^* \leq 0|x_i)E_{y|x,y=0}[y|x, y = 0] + Pr(y^* > 0|x_i)E_{y|x,y>0}[y|x, y > 0]$$

- The conditional expectations are:

$$E_{y_i|x_i,y_i>0}\left[y_i|\,x_i, y_i > 0\right] = x_i'\beta + \sigma \cdot \frac{\phi\left(\frac{x_i'\beta}{\sigma}\right)}{\Phi\left(\frac{x_i'\beta}{\sigma}\right)}.$$

and

$$\begin{aligned} E_{y_i|x_i}\left[y_i|\,x_i\right] &= \Pr\left(y^* > 0|\,x_i\right) \cdot E_{y_i|x_i,y_i>0}\left[y_i|\,x_i, y_i > 0\right] \\ &= \Phi\left(\frac{x_i'\beta}{\sigma}\right) \cdot \left[x_i'\beta + \sigma \cdot \frac{\phi\left(\frac{x_i'\beta}{\sigma}\right)}{\Phi\left(\frac{x_i'\beta}{\sigma}\right)}\right] \\ &= \Phi\left(\frac{x_i'\beta}{\sigma}\right) x_i'\beta + \phi\left(\frac{x_i'\beta}{\sigma}\right) \end{aligned}$$

Tobit: Heckman Two-Step Estimation

Define inverse Mills ratio:

$$\begin{aligned} \lambda\left(z\right) &= \frac{\phi\left(z\right)}{\Phi\left(z\right)} \\ \lambda\left(\frac{x_i'\beta}{\sigma}\right) &= \frac{\phi\left(\frac{x_i'\beta}{\sigma}\right)}{\Phi\left(\frac{x_i'\beta}{\sigma}\right)}. \end{aligned}$$

Tobit: Heckman Two-Step Estimation

Define inverse Mills ratio:

$$\begin{aligned}\lambda(z) &= \frac{\phi(z)}{\Phi(z)} \\ \lambda\left(\frac{x_i'\beta}{\sigma}\right) &= \frac{\phi\left(\frac{x_i'\beta}{\sigma}\right)}{\Phi\left(\frac{x_i'\beta}{\sigma}\right)}.\end{aligned}$$

Based on above equation, Heckman constructed the model equation for data that satisfy $y_i > 0$

$$y_i = x_i'\beta + \sigma \cdot \lambda\left(\frac{x_i'\beta}{\sigma}\right) + u_i$$

where the error term u_i has zero conditional expectation

$$E[u_i | x_i, y_i > 0] = 0.$$

We implement estimation with two steps.

Tobit: Heckman Two-Step Estimation

Step 1: Using all data and implement probit (or logit) estimation by using dummy variable (rewriting the definition of dummy variable d_i)

$$d_i = \begin{cases} 1 & : \text{ if } y_i > 0 \\ 0 & : \text{ if } y_i = 0 \end{cases},$$

and construct the probit (or logit) model

$$\begin{aligned} d_i &= x_i'\beta + \varepsilon_i \\ \underbrace{d_i}_{0 \text{ or } 1} &= x_i'\beta + \underbrace{\varepsilon_i}_{\text{distributed as } N(0,\sigma^2)} \end{aligned}.$$

Then, we can estimate (you know, in binary choice model, we can estimate β up to scale)

$$\widehat{\left(\frac{\beta}{\sigma}\right)},$$

by probit (or logit) estimation.

Step 2: Calculate the estimate of hazard function by using $\widehat{\left(\frac{\beta}{\sigma}\right)}$ in step 1

$$\lambda\widehat{\left(\frac{x_i'\beta}{\sigma}\right)} = \lambda\left(x_i'\widehat{\left(\frac{\beta}{\sigma}\right)}\right) = \frac{\phi\left(x_i'\widehat{\left(\frac{\beta}{\sigma}\right)}\right)}{\Phi\left(x_i'\widehat{\left(\frac{\beta}{\sigma}\right)}\right)}.$$

Then, implement OLS for the model by only using $y_i > 0$ data

$$y_i = x_i'\beta + \sigma \cdot \lambda\widehat{\left(\frac{x_i'\beta}{\sigma}\right)} + u_i,$$

and obtain estimator $\hat{\beta}$ and $\hat{\sigma}$.

Heckman Two-Step Estimation: A generalized tobit model

- The differences between Heckman selection model and tobit model are: (i) the predictors of dependent variables are not the same as the covariates $\mathbf{Z}$ that determine the selection in the first stage and (ii) errors of two stages are correlated.

Heckman Two-Step Estimation: A generalized tobit model

- The differences between Heckman selection model and tobit model are: (i) the predictors of dependent variables are not the same as the covariates $\mathbf{Z}$ that determine the selection in the first stage and (ii) errors of two stages are correlated.
- $$y_2 = Z\gamma + \mu_1,$$
  $$d = \begin{cases} 1 & \text{if } y_2 > 0 \\ 0 & \text{if } y_2 \leq 0 \end{cases}$$
  and
  $$Y_1 = X\beta + \nu_2 \text{ if } d = 1,$$
  where
  $$\begin{pmatrix} v_1 \\ \nu_2 \end{pmatrix} \sim N\left[\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} \sigma_1^2 & \rho\sigma_1 \\ \rho\sigma_1 & 1 \end{pmatrix}\right]$$

Heckman Two-Step Estimation: A generalized tobit model

- The differences between Heckman selection model and tobit model are: (i) the predictors of dependent variables are not the same as the covariates $\mathbf{Z}$ that determine the selection in the first stage and (ii) errors of two stages are correlated.
- $$y_2 = Z\gamma + \mu_1,$$
  $$d = \begin{cases} 1 & \text{if } y_2 > 0 \\ 0 & \text{if } y_2 \leq 0 \end{cases}$$
  and
  $$Y_1 = X\beta + \nu_2 \text{ if } d = 1,$$
  where
  $$\begin{pmatrix} v_1 \\ \nu_2 \end{pmatrix} \sim N\left[\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} \sigma_1^2 & \rho\sigma_1 \\ \rho\sigma_1 & 1 \end{pmatrix}\right]$$
- We can derive the conditional expectation
  $$E_{y_1|x,y_2>0}(y_1|x, y_2 > 0) = X\beta + \sigma_1\rho\lambda(Z'\gamma)$$

Heckman Two-Step Estimation: A generalized tobit model

- The differences between Heckman selection model and tobit model are: (i) the predictors of dependent variables are not the same as the covariates $\mathbf{Z}$ that determine the selection in the first stage and (ii) errors of two stages are correlated.

- $$y_2 = Z\gamma + \mu_1,$$
  $$d = \begin{cases} 1 & \text{if } y_2 > 0 \\ 0 & \text{if } y_2 \leq 0 \end{cases}$$
  and
  $$Y_1 = X\beta + \nu_2 \text{ if } d = 1,$$
  where
  $$\begin{pmatrix} v_1 \\ \nu_2 \end{pmatrix} \sim N\left[\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} \sigma_1^2 & \rho\sigma_1 \\ \rho\sigma_1 & 1 \end{pmatrix}\right]$$

- We can derive the conditional expectation
  $$E_{y_1|x,y_2>0}(y_1|x, y_2 > 0) = X\beta + \sigma_1\rho\lambda(Z'\gamma)$$
  Still two step implementation!

The key is to obtain the probability distribution of y_1 given $y_2 > 0$

$$
\begin{aligned}
\Pr(y_{1i}, y_{2i} &> 0|X,Z) = f(y_{1i})\Pr(y_{2i} > 0|y_{1i},X,Z) = f(\nu_{1i})\Pr(\nu_{2i} > -Z_i\delta|\nu_{1i},X,Z) \\
&= \frac{1}{\sigma_1}\phi\left(\frac{y_{1i}-X_i\beta}{\sigma_1}\right)\cdot\int_{-Z_i\delta}^{\infty} f(\nu_{2i}|\nu_{1i})d\nu_{2i} \\
&= \frac{1}{\sigma_1}\phi\left(\frac{y_{1i}-X_i\beta}{\sigma_1}\right)\cdot\int_{-Z_i\delta}^{\infty}\phi\left(\frac{\nu_{2i}-\frac{\rho}{\sigma_1}(y_{1i}-X_i\beta)}{\sqrt{1-\rho^2}}\right)d\nu_{2i} \\
&= \frac{1}{\sigma_1}\phi\left(\frac{y_{1i}-X_i\beta}{\sigma_1}\right)\cdot\left[1-\Phi\left(\frac{-Z_i\delta-\frac{\rho}{\sigma_1}(y_{1i}-X_i\beta)}{\sqrt{1-\rho^2}}\right)\right] \\
&= \frac{1}{\sigma_1}\phi\left(\frac{y_{1i}-X_i\beta}{\sigma_1}\right)\cdot\Phi\left(\frac{Z_i\delta+\frac{\rho}{\sigma_1}(y_{1i}-X_i\beta)}{\sqrt{1-\rho^2}}\right)
\end{aligned}
$$

Heckman Two-Step Estimation: full likelihood estimation

2. Those where y_1 is not observed and we know that $y_2 \leq 0$. For these observations, the likelihood function is just the marginal probability that $y_2 \leq 0$. We have no independent information on y_1. This probability is written as

$$\Pr(y_{2i} \leq 0) = \Pr(\nu_{2i} \leq -Z_i\delta) = \Phi\left(-Z_i\delta\right) = 1 - \Phi\left(Z_i\delta\right)$$

Therefore the log likelihood for the complete sample of observations is the following:

$$\log L(\beta, \delta, \rho, \sigma; thedata) = \sum_{i=1}^{N_0} \log\left[1 - \Phi\left(Z_i\delta\right)\right]$$
$$+ \sum_{i=N_0+1}^{N} \left[-\log\sigma_1 + \log\phi\left(\frac{y_{1i} - X_i\beta}{\sigma_1}\right) + \log\Phi\left(\frac{Z_i\delta + \frac{\rho}{\sigma_1}(y_{1i} - X_i\beta)}{\sqrt{1-\rho^2}}\right)\right]$$
